## The TRDP Light Library API Specification

### 1.1 General Information

#### 1.1.1 Purpose

The TRDP protocol has been defined as the standard communication protocol in IP-enabled trains. It allows communication via process data (periodically transmitted data using UDP/IP) and message data (client - server messaging using UDP/IP or TCP/IP) This document describes the light API of the TRDP Library.

#### 1.1.2 Scope

The intended audience of this document is the developers and project members of the TRDP project. TRDP Client Applications are programs using the TRDP protocol library to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.

#### 1.1.3 Related documents

- TCMS* Train Control Management System

## 1.2 Terminology

The API documented here is mainly concerned with three bodies of code:

- *TRDP Client Applications* (or 'client applications' for short): These are programs using the API to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.
- *TRDP Light Implementations* (or just 'TRDP implementation'): These are libraries realising the API as documented here. Programmers developing such implementations will find useful definitions about syntax and semantics of the API within this documentation.
- *VOS Subsystem* (Virtual Operating System): An OS and hardware abstraction layer which offers memory, networking, threading, queues and debug functions. The VOS API is documented here.

The following diagram shows how these pieces of software are interrelated.

Figure 1.1: Sample client workflow

## 1.3 Conventions of the API

The API comprises a set of C header files that can also be used from client applications written in C++. These header files are contained in a directory named `trdp/api` and a subdirectory called `trdp/vos/api` with declarations not topical to TRDP but needed by the stack. Client applications shall include these header files like:

```
#include "trdp_if_light.h"
```

and, if VOS functions are needed, also the corresponding headers:

```
#include "vos_thread.h"
```

for example.

The subdirectory `trdp/doc` contains files needed for the API documentation.

Generally client application source code including API headers will only compile if the parent directory of the `trdp` directory is part of the include path of the used compiler. No other subdirectories of the API should be added to the compiler's include path.

The client API doesn't support a "catch-all" header file that includes all declarations in one step; rather the client application has to include individual headers for each feature set it wants to use.

### 5.24.2 Function Documentation

#### 5.24.2.1 TRDP\_ERR\_T trdp\_pdCheck (PD\_HEADER\_T \*pPacket, UINT32 packetSize)

Check if the PD header values and the CRCs are sane.

#### Parameters:

- ← *pPacket* pointer to the packet to check
- ← *packetSize* max size to check

**Return values:*****TRDP\_NO\_ERR******TRDP\_CRC\_ERR***

Here is the call graph for this function:

**5.24.2.2 void trdp\_pdDataUpdate (PD\_ELE\_T \*pPacket)**

Add padding and update data CRC.

Here is the call graph for this function:

**5.24.2.3 TRDP\_ERR\_T trdp\_pdDistribute (PD\_ELE\_T \*pSndQueue)**

Distribute send time of PD packets over time.

The duration of PD packets on a 100MBit/s network ranges from 3us to 150us max. Because a cyclic thread scheduling below 5ms would put a too heavy load on the system, and PD packets cannot get larger than 1436 (+ UDP header), we will not account for differences in packet size. Another factor is the differences in intervals for different packets: We should only change the starting times of the packets within 1/2 the interval time. Otherwise a late addition of packets could lead to timeouts of already queued packets. Scheduling will be computed based on the smallest interval time.

**Parameters:**

← *pSndQueue* pointer to send queue

**Return values:*****TRDP\_NO\_ERR***

Here is the call graph for this function:

#### 5.24.2.4 void trdp\_pdInit (PD\_ELE\_T \* *pPacket*, TRDP\_MSG\_T *type*, UINT32 *topoCount*, UINT16 *subs*, UINT16 *offsetAddress*, UINT32 *replyComId*, UINT32 *replyIpAddress*)

Initialize/construct the packet Set the header infos.

##### Parameters:

- ← *pPacket* pointer to the packet element to init
- ← *type* type the packet
- ← *topoCount* topocount to use for PD frame
- ← *subs* subsAndReserve
- ← *offsetAddress* ladder offset
- ← *replyComId* Pull request comId
- ← *replyIpAddress* Pull request Ip

Here is the call graph for this function:

#### 5.24.2.5 TRDP\_ERR\_T trdp\_pdReceive (TRDP\_SESSION\_PT *appHandle*, INT32 *sock*)

Receiving PD messages Read the receive socket for arriving PDs, copy the packet to a new PD\_ELE\_T Check for protocol errors and compare the received data to the data in our receive queue.

If it is a new packet, check if it is a PD Request (PULL). If it is an update, exchange the existing entry with the new one Call user's callback if needed

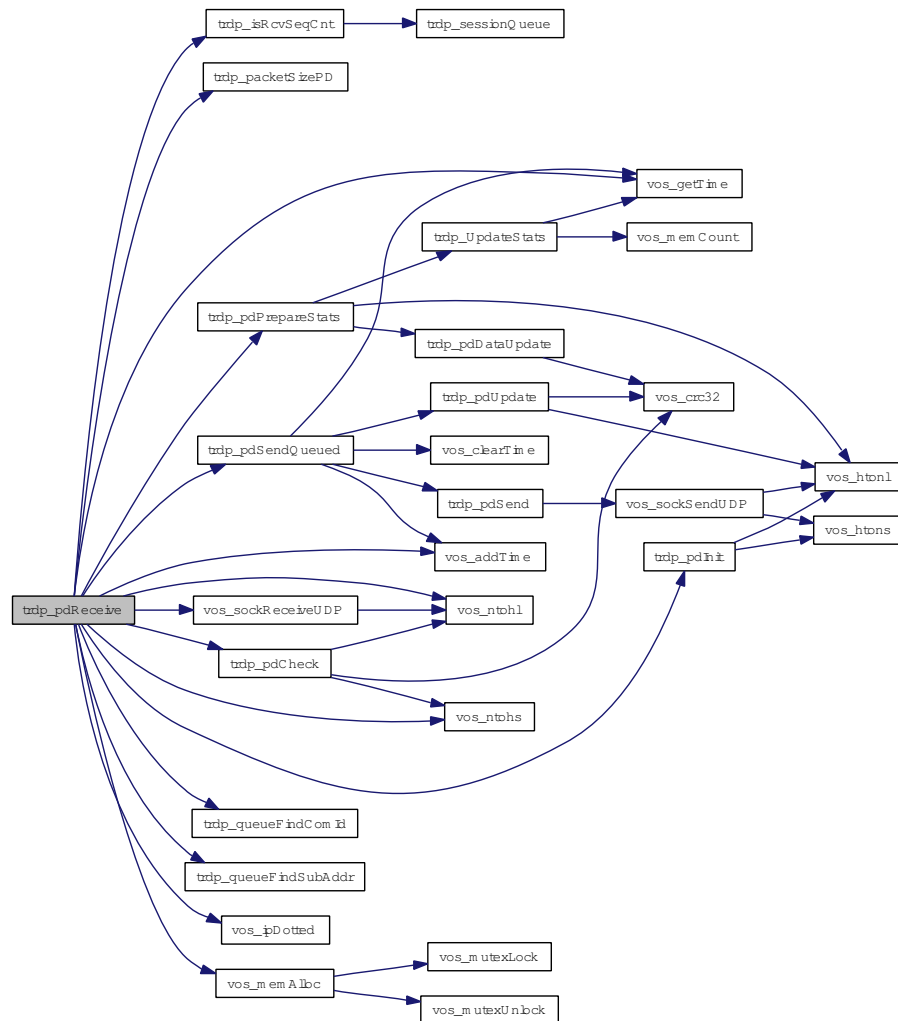

##### Parameters:

- ← *appHandle* session pointer
- ← *sock* the socket to read from

##### Return values:

- TRDP\_NO\_ERR** no error
- TRDP\_PARAM\_ERR** parameter error
- TRDP\_WIRE\_ERR** protocol error (late packet, version mismatch)
- TRDP\_QUEUE\_ERR** not in queue
- TRDP\_CRC\_ERR** header checksum
- TRDP\_TOPOCOUNT\_ERR** invalid topocount

Here is the call graph for this function:

#### 5.24.2.6 TRDP\_ERR\_T trdp\_pdSend (INT32 *pdSock*, PD\_ELEMENT \* *pPacket*, UINT16 *port*)

Send one PD packet.

##### Parameters:

- ← *pdSock* socket descriptor
- ← *pPacket* pointer to packet to be sent
- ← *port* port on which to send

##### Return values:

**TRDP\_NO\_ERR**

**TRDP\_IO\_ERR**

Here is the call graph for this function:

#### 5.24.2.7 TRDP\_ERR\_T trdp\_pdSendQueued (TRDP\_SESSION\_PT *appHandle*)

##### Parameters:

← *appHandle* session pointer

##### Return values:

### 5.34.2 Define Documentation

#### 5.34.2.1 #define VOS\_MEM\_BLOCKSIZEs

**Value:**

```
{32, 64, 128, 256, 512, 1024, 2048, 4096, 8192, \
    16384, 32768, 65536, 131072, 262144, 524288}
```

We internally allocate memory always by these block sizes.

The largest available block is 524288 Bytes, provided the overall size of the used memory allocation area is larger.

#### 5.34.2.2 #define VOS\_MEM\_PREALLOCATE {0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 1, 1, 4, 0, 0}

Default pre-allocation of free memory blocks.

To avoid problems with too many small blocks and no large one. Specify how many of each block size that should be pre-allocated (and freed!) to pre-segment the memory area.

Receive TCP data.

The caller must provide a sufficient sized buffer. If the supplied buffer is smaller than the bytes received, \*pSize will reflect the number of copied bytes and the call should be repeated until \*pSize is 0 (zero). If the socket was created in blocking-mode (default), then this call will block and will only return if data has been received or the socket was closed or an error occurred. If called in non-blocking mode, and no data is available, VOS\_NODATA\_ERR will be returned.

**Parameters:**

- ← *sock* socket descriptor
- *pBuffer* pointer to applications data buffer
- ↔ *pSize* pointer to the received data size

**Return values:**

- VOS\_NO\_ERR** no error
- VOS\_PARAM\_ERR** sock descriptor unknown, parameter error
