Chapter 1

The TRDP Light Library API Specification

1.1 General Information

1.1.1 Purpose

The TRDP protocol has been defined as the standard communication protocol in IP-enabled trains. It allows communication via process data (periodically transmitted data using UDP/IP) and message data (client - server messaging using UDP/IP or TCP/IP) This document describes the light API of the TRDP Library.

1.1.2 Scope

The intended audience of this document is the developers and project members of the TRDP project. TRDP Client Applications are programs using the TRDP protocol library to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.

| 1.2 | Terminology | | |

The API documented here is mainly concerned with three bodies of code:

- TRDP Client Applications (or 'client applications' for short): These are programs using the API to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.
- TRDP Light Implementations (or just 'TRDP implementation'): These are libraries realising the API as documented here. Programmers developing such implementations will find useful definitions about syntax and semantics of the API within this documentation.
- VOS Subsystem (Virtual Operating System): An OS and hardware abstraction layer which offers memory, networking, threading, queues and debug functions. The VOS API is documented here.

The following diagram shows how these pieces of software are interrelated.

1.3 Conventions of the API

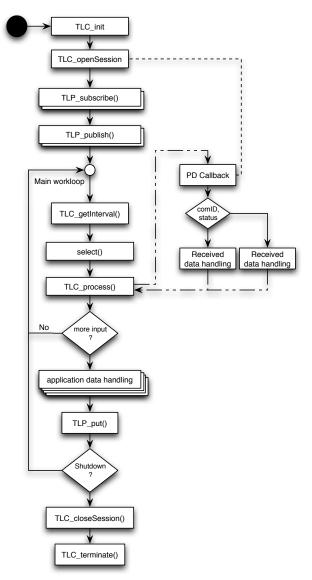

Figure 1.1 Sample client workflow

1.3 Conventions of the API

The API comprises a set of C header files that can also be used from client applications written in C++. These header files are contained in a directory named trdp/api and a subdirectory called trdp/vos/api with declarations not topical to TRDP but needed by the stack. Client applications shall include these header files like:

```
#include "trdp_if_light.h"
```

and, if VOS functions are needed, also the corresponding headers:

```
#include "vos_thread.h"
```

for example.

The subdirectory trdp/doc contains files needed for the API documentation.

Generally client application source code including API headers will only compile if the parent directory of the trdp directory is part of the include path of the used compiler. No other subdirectories of the API should be added to the compiler's include path.

The client API doesn't support a "catch-all" header file that includes all declarations in one step; rather the client application has to include individual headers for each feature set it wants to use.

5.11.1 Detailed Description

Functions for train topology information access.

The TTI subsystem maintains a pointer to the TAU_TTDB struct in the TRDP session struct. That TAU_TTDB struct keeps the subscription and listener handles, the current TTDB directories and a pointer list to consist infos (in network format). On init, most TTDB data is requested from the ECSP plus the own consist info. This data is automatically updated if an inauguration is detected. Additional consist infos are requested on demand, only. Because of the asynchronous behavior of the TTI subsystem, most functions in tau_tti.c may return TRDP_N← ODATA_ERR on first invocation. They should be called again after 1...3 seconds (3s is the timeout for most MD replies).

| in | pPacket | pointer to the packet to check |
|----|------------|--------------------------------|
| in | packetSize | max size to check |

Return values

| TRDP_NO_ERR | |
|--------------|--|
| TRDP_CRC_ERR | |

5.22.2.2 trdp_pdCheckListenSocks()

|--------|-----------|--|
| in | pRfds | pointer to set of ready descriptors |
| in,out | pCount | pointer to number of ready descriptors |

Here is the call graph for this function:

Parameters

| in | appHandle | session pointer |
|--------|-----------|--|
| in,out | pFileDesc | pointer to set of ready descriptors |
| in,out | pNoDesc | pointer to number of ready descriptors |

5.22.2.4 trdp_pdDistribute()

Distribute send time of PD packets over time.

The duration of PD packets on a 100MBit/s network ranges from 3us to 150us max. Because a cyclic thread scheduling below 5ms would put a too heavy load on the system, and PD packets cannot get larger than 1432 (+ UDP header), we will not account for differences in packet size. Another factor is the differences in intervals for different packets: We should only change the starting times of the packets within 1/2 the interval time. Otherwise a late addition of packets could lead to timeouts of already queued packets. Scheduling will be computed based on the smallest interval time.

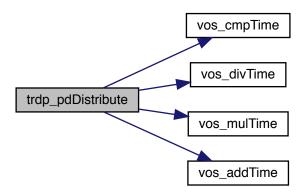

Parameters

| in | pSndQueue | pointer to send queue |
|----|-----------|-----------------------|

Return values

TRDP_NO_ERR

Here is the call graph for this function:

5.22.2.5 trdp_pdHandleTimeOuts()

5.33.2 Macro Definition Documentation

5.33.2.1 VOS MEM BLOCKSIZES

```

Value:

We internally allocate memory always by these block sizes.

The largest available block is 524288 Bytes, provided the overal size of the used memory allocation area is larger.

5.33.2.2 VOS_MEM_PREALLOCATE

```
#define VOS_MEM_PREALLOCATE {0u, 0u, 0u, 0u, 0u, 0u, 0u, 4u, 0u, 0u, 0u, 0u, 0u, 0u, 0u, 0u}
```

Default pre-allocation of free memory blocks.

To avoid problems with too many small blocks and no large one. Specify how many of each block size that should be pre-allocated (and freed!) to pre-segment the memory area.

5.39.3 Function Documentation

5.39.3.1 vos_crc32()

Calculate CRC for the given buffer and length.

For TRDP FCS CRC calculation the CRC32 according to IEEE802.3 with start value 0xffffffff is used.

Parameters

| in | crc | Initial value. |
|--------|---------|--------------------------|
| in,out | pData | Pointer to data. |
| in | dataLen | length in bytes of data. |

Return values

| crc32 | according to | |
|-------|--------------|--|
| | IEEE802.3 | |

Calculate CRC for the given buffer and length.

/ to IEC 61375-2-3 A.3 Note: Returned CRC is inverted

| in <i>crc</i> | Initial value. |
|---------------|----------------|
|---------------|----------------|

Parameters

| in,out | pData | Pointer to data. |
|--------|---------|--------------------------|
| in | dataLen | length in bytes of data. |

Return values

| crc32 | according to | |
|-------|--------------|--|
| | IEEE802.3 | |

5.39.3.2 vos_getErrorString()

Return a human readable error representation.

Parameters

| in error The TRDP or VOS error of | code |
|-----------------------------------|------|
|-----------------------------------|------|

Return values

| const | string pointer to error string |
|-------|--------------------------------|
|-------|--------------------------------|

5.39.3.3 vos_getVersion()

Return version.

Return pointer to version structure

Return values

Return pointer to version structure

Return values

```
VOS_VERSION←

```

5.39.3.4 vos_getVersionString()

Return a human readable version representation.

Return string in the form 'v.r.u.b'

Return values

| const | string |
|-------|--------|

5.39.3.5 vos_init()

Initialize the vos library.

This is used to set the output function for all VOS error and debug output.

Parameters

5.39.3.7 vos_terminate()

```
\begin{tabular}{lll} EXT\_DECL & void & vos\_terminate & ( & & void & ) \end{tabular}
```

Delnitialize the vos library.

Should be called last after TRDP stack/application does not use any VOS function anymore.
