Chapter 1

The TRDP Light Library API Specification

1.1 General Information

1.1.1 Purpose

The TRDP protocol has been defined as the standard communication protocol in IP-enabled trains. It allows communication via process data (periodically transmitted data using UDP/IP) and message data (client - server messaging using UDP/IP or TCP/IP) This document describes the light API of the TRDP Library.

1.1.2 Scope

The intended audience of this document is the developers and project members of the TRDP project. TRDP Client Applications are programs using the TRDP protocol library to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.

1.1.4	Abbreviations and Definitions		
-API	Application Programming Interface		
-ECN	V Ethernet Consist Network		
-TRE	DP Train Real-time Data Protocol		
-TCN	MS Train Control Management System		
1.2	Terminology		

The API documented here is mainly concerned with three bodies of code:

- TRDP Client Applications (or 'client applications' for short): These are programs using the API to access the services of TRDP. Programmers developing such applications are the main target audience for this documentation.
- TRDP Light Implementations (or just 'TRDP implementation'): These are libraries realising the API as documented here. Programmers developing such implementations will find useful definitions about syntax and semantics of the API within this documentation.
- VOS Subsystem (Virtual Operating System): An OS and hardware abstraction layer which offers memory, networking, threading, queues and debug functions. The VOS API is documented here.

The following diagram shows how these pieces of software are interrelated.

1.3 Conventions of the API

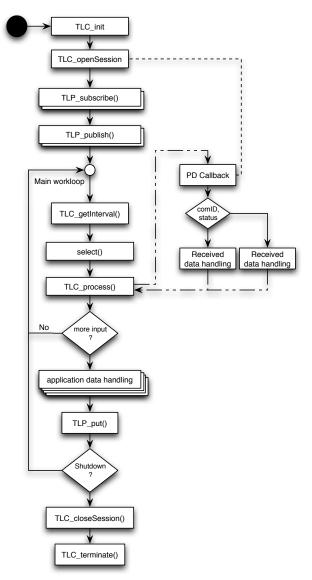

Figure 1.1 Sample client workflow

1.3 Conventions of the API

The API comprises a set of C header files that can also be used from client applications written in C++. These header files are contained in a directory named trdp/api and a subdirectory called trdp/vos/api with declarations not topical to TRDP but needed by the stack. Client applications shall include these header files like:

```
#include "trdp_if_light.h"
```

and, if VOS functions are needed, also the corresponding headers:

```
#include "vos_thread.h"
```

for example.

The subdirectory trdp/doc contains files needed for the API documentation.

Generally client application source code including API headers will only compile if the parent directory of the trdp directory is part of the include path of the used compiler. No other subdirectories of the API should be added to the compiler's include path.

The client API doesn't support a "catch-all" header file that includes all declarations in one step; rather the client application has to include individual headers for each feature set it wants to use.

5.10.1 Detailed Description

Functions for train topology information access.

The TTI subsystem maintains a pointer to the TAU_TTDB struct in the TRDP session struct. That TAU_TTDB struct keeps the subscription and listener handles, the current TTDB directories and a pointer list to consist infos (in network format). On init, most TTDB data is requested from the ECSP plus the own consist info. This data is automatically updated if an inauguration is detected. Additional consist infos are requested on demand, only.

5.21.2 Function Documentation

5.21.2.1 trdp_pdCheck()

Check if the PD header values and the CRCs are sane.

Parameters

in	pPacket	pointer to the packet to check
in	packetSize	max size to check

Return values

TRDP_NO_ERR	
TRDP_CRC_ERR	

5.21.2.2 trdp_pdCheckListenSocks()

Parameters

in	appHandle	session pointer

in,out	pCount	pointer to number of ready descriptors

Here is the call graph for this function:

5.21.2.3 trdp_pdCheckPending()

Check for pending packets, set FD if non blocking.

Parameters

in	appHandle	session pointer
in,out	pFileDesc	pointer to set of ready descriptors
in,out	pNoDesc	pointer to number of ready descriptors

5.21.2.4 trdp_pdDistribute()

```
TRDP_ERR_T trdp_pdDistribute ( \label{eq:pd_error} \texttt{PD\_ELE\_T} \ * \ pSndQueue \ )
```

Distribute send time of PD packets over time.

The duration of PD packets on a 100MBit/s network ranges from 3us to 150us max. Because a cyclic thread scheduling below 5ms would put a too heavy load on the system, and PD packets cannot get larger than 1432 (+ UDP header), we will not account for differences in packet size. Another factor is the differences in intervals for different packets: We should only change the starting times of the packets within 1/2 the interval time. Otherwise a late addition of packets could lead to timeouts of already queued packets. Scheduling will be computed based on the smallest interval time.

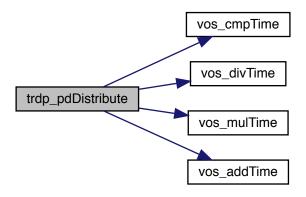

Parameters

in <i>pSndQueue</i>	pointer to send queue
---------------------	-----------------------

Return values

TRDP_NO_ERR

Here is the call graph for this function:

5.21.2.5 trdp_pdHandleTimeOuts()

If it is a new packet, check if it is a PD Request (PULL). If it is an update, exchange the existing entry with the new one Call user's callback if needed

Parameters

in	sock	the socket to read from

Return values

in	pBuf	Pointer to the array to search	
in	num	number of elements	
in	size	size of one element	
in	compare	Pointer to compare function return -n if arg1 < arg2, return 0 if arg1 == arg2, return +n if arg1	
		> arg2 where n is an integer != 0

UINT32 * pFreeMemory,

UINT32 * pMinFree,

UINT32 * pNumAllocBlocks,

UINT32 * pNumAllocErr,

UINT32 * pNumFreeErr,

UINT32 blockSize[VOS_MEM_NBLOCKSIZES],

5.31.2.4 vos_memDelete()

Delete the memory area.

This will eventually invalidate any previously allocated memory blocks! It should be called last before the application quits. No further access to the memory blocks is allowed after this call.

Parameters

in	pMemoryArea	Pointer to memory area used
----	-------------	-----------------------------

5.31.2.5 vos_memFree()
